**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# THÈSE POUR OBTENIR LE GRADE DE DOCTEUR DE L'UNIVERSITÉ DE MONTPELLIER

En Informatique

École doctorale Information, Structures, et Systèmes de Montpellier (I2S)

Unité de recherche Laboratoire d'Informatique, Robotique et Micro-électronique de Montpellier (LIRMM)

En partenariat international avec Faculté d'Informatique, Université du Caire, EGYPTÉ

## MONITORAGE DANS LES RESEAUX DE TYPE INTERNET DES OBJETS

Présentée par Basma Mostafa HASSAN

Le 20 Décembre 2019

Sous la direction de Miklos MOLNAR

# Declaration of Authorship

I, Basma Mostafa Abdelghany HASSAN, declare that this thesis titled, “Optimized Monitoring of Internet of Things Networks” and the work presented in it are my own. I confirm that:

- This work was done wholly or mainly while in candidature for the PhD research degree at Cairo University and the Université de Montpellier.
- Where any part of this thesis has previously been submitted for a degree or any other qualification at both universities or any other institution, this has been clearly stated.
- Where I have consulted the published work of others, this is always clearly attributed.
- Where I have quoted from the work of others, the source is always given. With the exception of such quotations, this thesis is entirely my own work.
- I have acknowledged all main sources of help.
- Where the thesis is based on work done by myself jointly with others, I have made clear exactly what was done by others and what I have contributed myself.

# Abstract

The research of this Ph.D. is fulfilled in the context of the optimized monitoring of Internet of Things (IoT) networks. The IoT enables the interconnection of billions of sensors, actuators, even humans to the Internet, creating a wide range of services, some of which are mission-critical. However, IoT networks are faulty in nature; Things are resource-constrained in terms of energy and computational capabilities. Moreover, they are connected via lossy links. For IoT systems performing a critical mission, it is crucial to ensure connectivity, availability, and network reliability, which requires *proactive* network monitoring. The idea is to oversee the network state and functioning of the nodes and links; to ensure the early detection of faults and decrease in node *unreachability times*. It is imperative to minimize the resulting monitoring energy consumption to allow the IoT network to perform its primary function. Furthermore, to realize the integration of the monitoring mechanism with IoT services, the proposed models should work in tandem with the IoT standardized protocols, especially the IPv6 for Low-power Wireless Personal Area Networks (6LoWPAN) and the Routing Protocol for Low-power and lossy networks (RPL). In this challenging context, the first step of analysis is to ensure the (*optimal*) placement of monitoring nodes (*monitors*) to cover the given domain. Leveraging the graph built by RPL (the DODAG), the monitoring coverage can be modeled as the classic Minimum Vertex Cover (MVC) on the DODAG. MVC is NP-hard on general graphs and polynomial-time solvable on trees. To reduce the computational complexity, we introduce an algorithm to convert the DODAG into *nice-tree* decomposition. We demonstrate that the monitor placement, in this case, is only Fixed-Parameter Tractable, and can also be polynomial-time solvable. The monitoring role should be distributed and balanced to prolong network longevity. To that end, assuming periodical functioning, we propose to assign Vertex Cover (VC) sets to time periods in a three-phase centralized monitoring approach. In the first phase, multiple minimal VC are computed. The assignment of the VC across the planning horizon is handled in the second phase; by modeling the scheduling as a multi-objective Generalized Assignment Problem (GAP). To minimize the state transitions in a duty-cycled monitoring approach, the optimal sequence between the sets of monitors across time periods is computed in phase three; by modeling it as a Traveling Salesman Path Problem (TSP-Path). In a third contribution, we provide the exact solution to the defined monitoring placement and scheduling problem via formulating a Binary Integer Program. The model serves as a benchmark for the performance evaluation of contemporary models. Moreover, the monitoring mechanism must adapt to real-time network instabilities. Therefore, in our final contribution, we propose a dynamic distributed monitoring scheduling mechanism, which is implemented in the Contiki OS for constrained networks, and experimented using the COOJA simulator; the *de facto* simulator for IoT applications. Results demonstrate the models' effectiveness in realizing full monitoring coverage with minimum energy consumption and communication overhead, and a balanced distributed monitoring role.

# Acknowledgements

The author Basma Mostafa would like to thank the French Ministry of Foreign Affairs, the Embassy of France in Egypt, the French Institute in Egypt for their grant, and the Egyptian Ministry of Higher Education and Scientific Research. Also, she would like to thank the L'Oreal foundation and UNESCO for their award in the 2017 L'Oreal-UNESCO for Women in Science Levant and Egypt Fellowship.
